I. NUMBER OF WOMEN WORKERS

Long-Term Trend

According to the 1950 Census of Population, the number of women in the total labor force in 1950 was about $4\frac{1}{2}$ times as large as the number who were working in 1890. Many factors have contributed to the tremendous increase in the number of working women in this country, and one of the most basic has been the growth in the population.

During the past 60 years, the number of persons in the population of working age (14 years and over) has almost tripled. The increase in the number of women during these years has been slightly greater than the increase in the number of men. In 1890, women

were a little less than half of the population 14 years and over; in 1950, when they numbered 57 million, women were a little more than half of this population.

Whereas the woman population almost tripled during these years, the woman labor force more than quadrupled. Population growth alone, therefore, does not account for the number of women workers today, by comparison with 1890. At the same time there has been an increasing proportion of women engaged in work outside of their homes, a proportion which has risen by more than 50 percent from 1890 to 1950. In 1890, less than 20 percent of the woman

population 14 years and over were in the labor force. At this rate, women workers would have numbered only about $10\frac{1}{2}$ million in 1950, or about two-thirds of the number actually reported (table 1).

Underlying this trend toward the increasing participation of women in the market place have been significant changes in the economic life of the Nation, and in the social customs and modes of living of the people. Most of the productive activities of the country have been transferred from home to factory; but women's work is still required to perform them. Furthermore, this change requires increased money income in the family in order to obtain the goods and services which were formerly provided by unpaid labor in the home.

Additional factors which have contributed to and are reflected in the growth in the proportion of women who work outside of their homes have been the trend toward urbanization and the concomitant increase in apartment-house living, a declining birthrate (at least until recent years), and increasing education for women which has fitted them for a variety of new jobs.

This increasing tendency for women to work occurred along with a declining proportion of men who were working: Between 1890 and 1950, the number of men in the labor force more than doubled, but this was slightly less than the

growth in the male population of working age during these years. In other words, the proportion of men who were working in 1950 (79 percent) was somewhat less than the proportion who were working in 1890 (84 percent). As a consequence, in 1890, almost 2 out of every 10 workers were women; in 1950, about 3 out of every 10 workers were women (table 1).

Changes Since 1940

The changes which have occurred in the woman labor force since 1940 represent a continuation of the long-term trend toward an increasing proportion of women in the Nation's civilian work force. This trend was, of course, accelerated by the stimulus of World War II. During the war years, women's work outside of the home was required to perform not only those jobs which were customarily carried on by women, but also those jobs which were vacated by men who were inducted into the armed services.

In March 1940, before World War II, there had been about 14 million working women in the United States. At that time, 28 percent of all women 14 years and over in the population were in the labor force; and they formed one-fourth of all workers. By April 1945, after more than 3 years of war, there were $19\frac{1}{2}$ million women in the labor force. Thirty-seven percent of the women of working age were working; and more than a third of the civilian workers were women.

This dramatic increase in the woman labor force in a 5-year period was directly attributable, of course, to World War II. Following the war, men were discharged from the armed services to resume civilian jobs, and the Nation adjusted to a postwar economy. This was accompanied by an exodus of women from the labor force, families were reunited, and the birthrate increased sharply. A postwar low point in the participation of women in the Nation's work force was reached by 1947, when 16 million women, or 30 percent of the woman population of working age were in the labor force. Even in 1947, however, the proportion of the Nation's workers who were women was 2 points above the 1940 level (table 2).

Following the postwar low year of 1947, the rising cost of living and the ever-pressing family need for additional money income forced many women back into the labor force. In addition, of course, increased employment opportunities as a result of wartime labor-force experience were undoubtedly an encouragement to many women to seek employment outside of the home. Average annual employment of women during the year 1950 was 18.7 million, or one-third of the woman population. These women formed 30 percent of all civilian workers.

Since, in the main, all men of working age who are able to work are already in the labor force, any crisis in our national life which requires the expansion of the civilian labor force or the Armed Forces must result in additional numbers of women

finding employment outside of their homes. During 1951, as a result of such a crisis in Korea, the number of women in the labor force averaged 19.3 million, by comparison with 18.7 million during the previous year. This growth in the number of women workers was responsible for maintaining the civilian labor force at approximately its pre-Korean level, in spite of the induction of large numbers of young men into the armed services (table 3).

During the year 1952, there were - on the average - $19\frac{1}{2}$ million women, or more than a third of the woman population, in the labor force. This number, though not the proportion of the woman population, exceeded the average for the wartime year of 1944 (table 3),

In recent months there appears to have been some levelling-off in the need to utilize women as replacements for male civilian workers. April 1953 figures show just under 19 million women in the labor force.

II. OCCUPATIONS

In April 1953, better than 1 out every 4 women who were working - more than 5 million women - were employed in clerical occupations. One out of every 5 women employed, or almost 4 million women, were operatives or factory workers. These two occupational groups accounted for almost half of all employed women in the spring of 1953. Service workers, professional or technical workers, and private household workers each accounted for about another 2 million women; the saleswoman group employed about $1\frac{1}{2}$ million women. Other occupational groups each had less than a million women.

Since 1940 there have been a number of significant changes in the kinds of jobs that women hold and in the proportion of women workers who are in each type of occupation:

Clerical Workers

Certainly the most dramatic change since 1940 has been the increase in the number of women clerical workers - from $2\frac{1}{2}$ million in 1940 to more than 5 million in 1953. Although the number of women clerical workers declined slightly following World War II, by 1951 - with the impact of the Korean crisis - the number had exceeded the previous wartime peak. Today the number of women clerical workers is about the same as it was at the height of World War II (table 4).

As the number of clerical workers has increased, the proportion of women who find employment in these jobs has also increased. In 1940, 1 out of every 5 employed women was a clerical worker; in 1953, 1 out of every 4 women was in this kind of job. Among employed men, on the other hand, less than 1 out of 15 is a clerical worker, and this proportion has varied only slightly since 1940 (table 6).

Of the 5 million men and women clerical workers in 1940, slightly more than half were women. In 1945, 7 out of 10 clerical workers were women. Following the war, of course, the proportion of women in these occupations declined from its wartime peak; but the effect of this wartime experience persisted in that the proportion of women in clerical jobs remained considerably above the prewar level. In 1953 almost two-thirds of the clerical workers were women (table 5).

Private Household Workers

Probably the most important change which has occurred in the occupational pattern of employed women since 1940 is that today only 10 percent of employed women are in private household work, whereas 18 percent were in this occupation before the war. That the proportion engaged in private household work declines as other job opportunities increase is evidenced by the fact that during the

war, when the demand for women in defense industries was greater than today, the proportion of women in private household work was even lower (table 6).

In 1940, out of a total of 12 million employed women, there were 2 million private household workers. In 1945, while World War II was still in process, there were only about $1\frac{1}{2}$ million private household workers, out of a total of more than 19 million employed women (table 4). Although more women were working in these low-paying jobs following World War II, neither the number nor proportion of women so employed has risen to the prewar level. In 1940, the number of women household workers was the same as the number of women operatives. In 1953, there were more than twice as many women operatives as private household workers.

Today, almost all private household workers are women. Only about 3 percent of the persons engaged in this occupation are men, whereas in 1940, about 6 percent were men (table 5).

Professional and Technical Workers

In April 1953 there were approximately 2 million women employed as teachers, nurses, welfare workers, librarians, medical technicians, and in similar professional and technical jobs. These women numbered over $1/3$ million more than were similarly engaged in 1940 (table 4).

Despite this increase in the number of women professional and technical workers there has

been a decline in the proportion of women who find employment in these jobs today, by comparison with 1940; and during World War II the decline was even greater. In 1940, about 13 percent of all employed women were professional or technical workers. During the war, in 1945, this proportion dropped to 8 percent. Today, 1 out of every 10 employed women is a professional or technical worker (table 6). These changes may be accounted for, in part, by the fact that, during the war when jobs were plentiful, many more women entered employment directly without spending years in the necessary professional or technical training. Also, some women may have left low-paying professional jobs for more remunerative work in other occupations.

In 1940, the $1\frac{1}{2}$ million women in professional and technical occupations were a little less than half of all such workers. Today the 2 million women in these jobs are only slightly more than a third of all such workers (table 5).

Operatives

In 1953, women operatives, most of whom are semiskilled factory workers, constituted the second largest group of employed women, following only women clerical workers. One-and-a-half million more women are employed in these jobs today than were so employed in 1940. The number today, however, is about $3/4$ of a million less than were employed during World War II. The number of women who have found employment as operatives since 1940 has fluctuated in accordance with the expanded manpower needs of defense industries and the size

of our Armed Forces. When men returned from military service and defense production was curtailed following World War II, the number of women operatives dropped from $4\frac{1}{2}$ million in 1945 to less than $3\frac{1}{2}$ million by 1947. Again, between 1950 and 1951, as a result of the Korean crisis, the number of women operatives increased by $\frac{1}{2}$ million - the sharpest year-to-year increase which has occurred since the end of World War II (table 4).

The changes in the proportion of employed women in factory jobs since 1940 have been less dramatic than the numerical changes. Since 1940 about a fifth of all employed women have held factory jobs, except, of course, during World War II, when almost a fourth of all employed women were working as operatives (table 6).

Likewise, the proportion of operatives who were women has shown little change since 1940, when about a fourth of all such workers were women; except, again, during the wartime year of 1945, when almost two-fifths of the factory production workers were women (table 5).

Farm Workers

Another occupational group in which the employment of women fluctuates sharply in accordance with national emergencies is that of farm workers. (Most women engaged in farm work are employed as farm laborers and not as farmers or farm managers.) In March 1940, about $\frac{2}{3}$ million

women were employed in farm work, and they formed less than a tenth of all such workers. In April 1945, almost 2 million women were working on farms and they constituted more than a fifth of all such workers. Since the war, with the exception of 1949 when they numbered 1 million, the number of women farm workers has declined steadily, and is not almost at the 1940 level (tables 4 and 5).

In 1940, only about 5 percent of all employed women, but almost 25 percent of all employed men, were working on farms. During the war, the proportion of women engaged in farm work about doubled as women replaced men called to armed service and the proportion of men in farm work consequently declined. Following the war, the proportion of women engaged in farm work returned to its prewar level, while the proportion of men so employed has steadily declined and today is only half of what it was in 1940.

Service Workers Except Private Household

Service workers include such persons as waitresses, cooks, hospital attendants, beauticians, elevator operators, practical nurses, and so forth. The number of women employed in these jobs has almost doubled since 1940; and today there are more than 2 million women engaged in the service occupations (table 4).

In 1940, two-fifths of the persons employed in the service occupations were women. During the war almost half of these employees were women.

The proportion of women declined immediately following World War II; but since 1949 it has been increasing again and today it is close to the war-time peak (table 5).

Little change has occurred in the percent of employed women or men who find jobs in these service occupations. About 7 percent of employed men and 13 percent of employed women work in service jobs today; and these proportions are approximately the same as in 1940 (table 6).

Sales Workers

As with service workers, the number of women salespersons has almost doubled since 1940. Today there are almost $1\frac{1}{2}$ million women employed in these jobs (table 4).

Little change has occurred in the proportion of employed women or men engaged in sales work - about 8 percent of the women and 5 percent of the men are working in these jobs today - almost the same proportion as were employed in 1940 (table 6).

During the war women formed more than half of all salespersons, by comparison with their 1940 proportion of slightly more than a quarter of all such workers. Today women are about two-fifths of all sales workers, a proportion they have maintained throughout the postwar period.

Craftsmen

Relatively few women are employed as craftsmen or foremen. They numbered about 250 thousand in

April 1953, and only 300 thousand at the height of World War II (table 4). These jobs occupy about 20 percent of all employed men but only about 2 percent of employed women (table 6).

During World War II women constituted almost 5 percent of all craftsmen and foremen, when the shortage of trained men forced the opening of some of these jobs to women. Following the war, however, women resumed their traditional proportion of 2 or 3 percent of all such workers.

Managers, Officials, and Proprietors

Almost a million women were employed as managers, officials, or proprietors in April 1953. This was almost double the number of women in such jobs in 1940 (table 4).

The proportion of employed women in these jobs is about half that of men, and the proportion has increased only slightly for both women and men since 1940 (table 6).

During World War II women formed about 17 percent of all managers, officials, and proprietors, an increase of 5 percentage points over their proportion in 1940. Today they are only 2 points below their 1945 level, although there have been some fluctuations in the intervening years (table 5).

III. INDUSTRY AND CLASS OF WORKER

Class of Worker in Nonagricultural and Agricultural Employment

Since 1940, at least four-fifths of all employed women have been wage and salary workers, and the remainder have been self-employed or unpaid family workers. Figures differentiating self-employed women from unpaid women family workers have been available only since 1946; and these figures indicate that less than 10 percent of the women who are in the labor force are self-employed. In 1953, these women were only 6 percent of all employed women. Among all employed workers, both women and men, the combined group of the self-employed and the unpaid family workers has declined from a fourth of all workers in 1940 to less than a fifth in 1953. Women were 14 percent of all self-employed and unpaid family workers in 1940. In 1945, when women were apparently caring for the business enterprises of their soldier-husbands, this proportion rose to 28 percent. In 1953, women accounted for 20 percent of all self-employed persons and unpaid family workers combined (table 7).

About 95 percent of all employed women work in nonagricultural industries. Almost all of these women are wage and salary workers; only about 6 percent are self-employed. Among the wage and salary workers, more than $2\frac{1}{4}$ million women are employees of Federal, State, or local governments; almost another 2 million are in private household work; and the remaining 12 million are wage or salary workers in private employment (table 7).

Only about 5 percent of all employed women, or less than 1 million, work in agriculture. During the spring and summer and the fall harvesting seasons, this number almost doubles.

In off-season months roughly from 10 to 15 percent of the persons in agriculture are women. In the harvesting seasons, however, this proportion may be as high as one-fourth of all workers. Depending upon the season of the year, from more

than a half to almost three-fourths of women farm workers may be unpaid family workers who do farm work for at least 15 hours a week (table 7).

Major Industry Distribution

Four major industry groups - manufacturing, retail trade, professional and related services, and personal services - accounted for the employment of more than three-fourths of all women workers in both 1940 and 1952. Within this period of time, however, a significant change had occurred in the distribution of women within these four groups: Whereas in 1940, a quarter of all women were employed in personal services and only a fifth in manufacturing industries, by 1952 these proportions were more than reversed, with nearly a quarter in manufacturing and less than a sixth in personal services (table 8).

In manufacturing, the proportion women were of all workers had increased only slightly between 1940 and 1952. During this same period, however, the proportion women formed of retail trade workers increased 10 points - from less than a third to two-fifths of all such workers (table 8). Although the proportion of workers in personal services who were women declined during the 12-year period, women were still almost three-fourths of all employees in the industry.

Not more than 5 percent - less than a million women - were employed in each of the remaining major industry groups in 1952. However, the proportion women were of all workers in these industries increased within the decade; and in 1952, women were two-fifths of all employees in finance, insurance, and real estate, and about a quarter of all persons employed in entertainment and recreation and of all public administration employees (table 8).

Manufacturing Industries

Four industries accounted for the employment of more than half of the 4.6 million women in manufacturing industries in March 1953. These industries were the following: Apparel and other finished textile products, with almost a million women; textile-mill products, and electrical machinery, each with more than half a million women; and food products, with slightly more than one-third million women (table 9).

Since 1950, only relatively small changes have occurred in the industry distribution of women in manufacturing. However, the cumulative effects of these changes have been sufficient to produce a noticeable change in the "durable-non-durable" distribution of women: In 1950, more than two-thirds of the women were engaged in the production of soft goods - apparel, textiles,

food, leather goods, etc.; and the remainder were engaged in heavy industries, such as machinery, transportation equipment, fabricated metal products, ordnance, etc. By 1953, reflecting the stepped-up production for defense purposes, the proportion of women employed in durable goods had increased 9 points, to 42 percent; and the proportion in nondurable goods had declined 8 points, to 58 percent.

The most dramatic increase in the employment of women in heavy industries was in ordnance and accessories. From only 4 thousand women in 1950, the number of employed women increased to 51 thousand women in 1953, or from only 17 percent of all ordnance workers to 27 percent of all workers in this field (tables 9 and 10).

Women were three-fourths of all workers in apparel manufacturing, nearly three-fifths of all workers in tobacco manufactures, and a third or more of all workers in textile, electrical machinery, leather products, instruments, and miscellaneous manufactures, in March 1953 (table 10).

Data are not available from the same source to indicate how many of the women employed in manufacturing are production workers, and how many are clerical, administrative, and supervisory workers. According to the 1947 Census of Manufactures, however, 81 percent of all women

and 84 percent of all men in manufacturing were production workers. For women, this proportion ranged from a high of 94 percent or more in tobacco, textile, and apparel manufacturing, to a low of 46 percent or less in primary metals, printing and publishing, and petroleum and coal products manufacturing, the latter with less than a quarter of the women employed as production workers.

During World War II, of course, it was as production workers, particularly in the durable-goods industries, that women were added to the labor force in such impressive numbers, to reach a wartime peak in November 1943 of 5 million women in all manufacturing industries, double the number who were so employed before the war. Women rose from only 8 percent of all durable-goods production workers in October 1940 to 24 percent of all such workers in 1943. In nondurable-goods industries women increased from 39 to 45 percent of all production workers during this period.

Federal Government Employment

In June 1952, there were slightly more than $\frac{1}{2}$ million women working for the Federal Government in civilian jobs. These women constituted about a fourth of all Government workers (table 11).

In 1923, the first year for which data are

available by sex, there were only 80 thousand women in the Federal service and they formed only a sixth of all Government workers. Their numbers increased slowly in subsequent years and in June 1941, before Pearl Harbor, there were only 266 thousand women in Federal jobs, a fifth of all Federal workers (table 11).

Necessity temporarily opened the Federal service to women, and 2 years after the outbreak of war their numbers approached 1 million; this was more than a third of all Federal civilian workers, better than double the proportion they had formed 10 years earlier.

Immediately following the war, of course, the size of the Federal civilian service declined by 20 percent, but the number of women employed declined by 40 percent. In 1945, women were 38 percent of all Federal workers. In 1946, women were displaced by men, many of whom were now eligible for veterans' preference in the Federal service; and the proportion of women declined to 28 percent. Today, women are only a fourth of all Federal workers (table 11).

Employment Among Farm Women

In April 1952, there were about 8 million women, 14 percent of the woman population, who

were living on farms. Only about a fifth of these women - about $1\frac{1}{2}$ million - were employed. More than half of this group were in nonagricultural industries (table 12). However, April is not a month of high seasonal employment among farm workers; therefore, these figures fail to show that during the harvesting seasons many additional farm women will be engaged as unpaid family workers on family farms. (See ch. II, Occupations - Farm Workers.)

Limited employment opportunities for farm women is probably one of the factors involved in the shift in population from rural to urban areas. This population shift has been a significant development in this country in the last decade. According to the 1950 decennial census, the proportion of the woman population living in rural farm areas was reduced from a fifth to an eighth between 1940 and 1950. The proportion of women living in urban areas, on the other hand, increased from three-fifths to two-thirds during this period. The residential distribution of the woman labor force, of course, followed a similar pattern (table 13).

Although the labor force participation rate of women living in rural farm areas increased during the decade, **in 1950 it was only 16 percent, half the worker rate for women living in urban areas (table 13).**

IV. UNEMPLOYMENT

Persons who are not working, either because they are not able or do not wish to work, are not considered part of the labor force and, therefore, are not among those classified as "unemployed." In April 1953, unemployed women, those actually seeking work, numbered almost $\frac{1}{2}$ million; however, these women represented only $2\frac{1}{2}$ percent of all women in the labor force. Furthermore, at that time women formed no greater proportion of the unemployed than of the employed.

Numbers

Since 1940, unemployment among women has dropped from about 2 million to less than $\frac{1}{2}$ million, the low point being approximately $\frac{1}{4}$ million during the war years 1944 and 1945. Beginning with the postwar year 1946, the number of unemployed women fast began to approach the 1 million mark, until 1951 when the employment effects of the Korean crisis caused a reversal of this trend, bringing the number down again to the post-World War II level of $\frac{1}{2}$ million.

In Contrast to Men

Traditionally, the unemployment rate for men is higher than for women; however, this pattern has been subject to deviations when men are being inducted into or released from the Armed Forces. As one might expect, the unemployment rates for both men and women were at their lowest during World War II, but slightly higher for women than for men because war-occasioned job opportunities brought large numbers of women into the labor force to seek work. The postwar period (1946 to 1950), however, showed the traditional picture, with unemployment rates for men, who were

returning from the armed services and seeking civilian jobs, noticeably higher than for women, many of whom were leaving the labor force following the war. With the advent of the Korean crisis, the picture was again reversed, and the rate for women exceeded that for men. Like the World War II picture, this development unquestionably resulted from the influx of women into the labor market for the purpose of securing jobs expected to arise from defense expansion.

Women Among the Employed and Unemployed

The proportion which women form of all employed persons has risen steadily since 1940, from about $\frac{1}{4}$ to almost $\frac{1}{3}$ of the total; the only marked fluctuation in this trend has been the definite increase during World War II. Among the unemployed, however, no such steady or clear trend is evident. Rather, the proportion which women form of the unemployed has shown a number of fluctuations which are directly related to expansion and contraction of the labor market: The proportion rose sharply during World War II, fell sharply after the war and rose sharply again with the Korean engagement. This reflects clearly the tendency of a sizable segment of the woman population to enter the labor force during times of emergency, and withdraw when heavy demands for labor have subsided or not materialized. However, in view of the small but steady increase in women's proportion of the employed, it is also clear that some of these new entrants become permanent members of the labor force.

V. LABOR TURNOVER AND LENGTH OF TIME ON THE JOB

Labor Turnover in Selected Manufacturing Industries

The rate at which persons voluntarily quit their jobs is affected by the availability of other jobs. Following the Korean crisis, as employment in defense-connected industries expanded, the quit rate for women increased. For the month of April 1950, just prior to the Korean outbreak, women were quitting their jobs at a rate of 18 per 1,000 women employees. In April 1951, this rate had increased to 26, and in April 1952 it was 24.

Moreover, in 1950 the rate for involuntary separations among women - layoffs, discharges, etc. - was about the same as the rate for voluntary separations, or 17 women per 1,000 women employees. In April 1951, however, while the quit rate for women was 26 per 1,000 women, the involuntary separation rate was 20 per 1,000. In April 1952, the rates on voluntary and involuntary separations for women were 24 and 21 (per 1,000 employees), respectively (table 15).

Hiring of women workers in manufacturing plants was, of course, considerably stimulated by the Korean crisis. The rate of hiring changed from 35 women per 1,000 employees in April 1950 to 45 women per 1,000 employees in April 1951, or an increase of almost 30 percent. In April 1952, there was a decline in the hiring rate by comparison with 1951, but the rate was still 17 percent above what it had been in April 1950 (table 15).

Turnover Among Women and Men

Labor turnover rates for men and women separately are available for 20 manufacturing industries. These rates for April 1952 indicate that in those durable-

goods industries for which rates are available voluntary separations among men and women occurred at the same rate, namely 23 per 1,000 employees. In two individual industries within the durable-goods group, quit rates were higher for women than for men: In electrical machinery and in instrument manufacturing (table 16).

In the nine other heavy industries for which rates were reported, quit rates were approximately the same for women as for men, with the following two exceptions: In furniture manufacturing, where women are about a fifth of all workers, the women's quit rate was substantially lower than men's. In lumber manufacturing (primarily a man-employing industry) the men's quit rates were substantially higher than the rates for women (table 16).

In nondurable-goods industries, on the other hand, the overall quit rates for the industries reported are considerably higher for women than for men - respectively, 26 and 18 per 1,000 employees. Women quit their jobs at a somewhat higher rate than men in the large women-employing industries of apparel, tobacco, and leather manufacturing. (About 50 percent or more of all of the employees in these industries are women.) Women also leave their jobs voluntarily at a higher rate than men in the rubber, paper, chemical, and petroleum-products manufacturing industries. With the exception of petroleum products, between a fourth and a fifth of all employees in these industries are women (table 16).

The common generalization, then, that quit rates for women are consistently higher than for men is obviously in need of certain modifications. Differences in the rates between women and men in the durable and nondurable industries suggest that the relatively lower wage rates in the large woman-employing industries may be an important factor in explaining some of the turnover among women workers.

In industries in which women were about a fifth of all employees, involuntary separations from factory jobs - layoffs, discharges, etc., - were higher for women than for men in four durable-goods industries in April 1952 - electrical machinery, instruments, fabricated metal products, and miscellaneous manufacturing; and in three nondurable-goods industries, namely rubber, food, and paper manufacturing. Involuntary separation rates for men were higher than for women in ordnance and furniture manufacturing, among the durable-goods industries; and in apparel, textile, tobacco, chemical and leather manufacturing among the soft-goods industries.

Length of Time on the Job

A January 1951 survey by the U. S. Bureau of the Census revealed that men, on the average, had been employed about 4 years at the job which they were holding at the time of the survey, whereas women had been employed only a little more than half as long at their current job (table 17).

Part of this difference is accounted for by the fact that the woman labor force, on the whole, is slightly younger than the male labor force. However, it must also be noted that the greatest discrepancies between men and women in length of

time on the job exist in the upper age groups. In fact, women 20 to 24 years of age are inclined to stay with the same employer to a somewhat greater extent than men. Among women in the older age groups, however, there were many who had left the labor market to assume full-time homemaking responsibilities, and who did not return to jobs outside of their homes until they had reached their middle years. Thus, women 55 to 64 years had been employed at the same job for only half as long as men in the same age groups (table 17).

Single women, primarily because they are younger women, had been with the same employer for an average of only 2 years. Married women without children under 18 years of age, on the other hand, had an average time of almost 3 years on the job, only a year less than that for men. Mothers of young children under 6 years of age, as might be expected, showed the lowest median years on the job - less than 1 year (table 17).

Among women, private household workers, service workers, and sales workers showed the lowest, and farm workers the highest, average time on the same job. Among men, farm laborers and other laborers were the least stable employees, with farmers, and managers and officials showing the most stability. Though relatively few women are employed as craftsmen their average time with the same employer was equal to men's. Interestingly enough, the stability of women operatives was not very much less than that of men operatives. Among men and women clerical workers, however, men had been with the same employer for a considerably longer period of time than women. Men in this occupation are older as a group than are the women so employed; and, in addition, men probably were offered more opportunities for advancement in their jobs (table 18).

1/ Current job was defined for all workers as a continuous period of employment, but with the following variations for different classes of workers: For wage and salary workers - with a single employer; odd job workers - at the particular type of job; self-employed - in a particular type of business or professional practice in the same locality; and unpaid workers - on the family-operated farm or business. In government employment, different agencies or bureaus were considered as different employers.

VI. AGE

Between 1890 and 1950 the population of working age (14 years and over) underwent important changes in size, sex composition, and age distribution. The size of the population of working age increased almost threefold, from 42 million to 113 million, with women accounting for a slightly larger proportion of the increase than men. The sex composition was reversed. In 1890, men in the working-age groups outnumbered women by more than 1 million; in 1950, women in these groups outnumbered men by almost $1\frac{1}{2}$ million. Most significantly, the number of men and women 45 years and over increased substantially more than the number under 45: Whereas men and women 45 years and over quadrupled in number, those under 45 only doubled.

Long-Term Labor Force Changes

Like the population, the labor force increased almost threefold between 1890 and 1950 - from 22 million to more than 60 million. Changes in the sex and age composition of the labor force were substantially more pronounced than in the population. The number of women in the labor force increased approximately

$4\frac{1}{2}$ times, while the number of men increased about $2\frac{1}{2}$ times. The greater proportion of both of these increases was in age groups 45 years and over, with women in these ages showing an almost ninefold increase. Thus, the number of women 45 years and over increased 4 times in the population, but almost 9 times in the labor force (table 19).

In view of this tremendous increase in the number of older women who were working, it is understandable that the median age of women workers advanced from 25 years in 1890 to 36 years in 1950, the most rapid change taking place between 1940 and 1950 when World War II created many additional job opportunities for women. Although the median age for men in the labor force advanced during this period, it was a much smaller change, from 34 years to 39 years. The median age of women workers today is only 3 years below that of men workers; whereas in 1890, it was 9 years (table 19).

Almost 1 out of every 3 women of working wage was in the labor force in 1950, as contrasted with less than 1 out of every 5 in 1890. The proportion of women in the population who work increased since 1890 in every age group, except 14 to 19 years. Almost three times the proportion of women between 35 and 54 years of age and twice the proportion of women 25 to 34 and 55 to 64 were working in 1950. Clearly then, it was women between the ages of 35 and 54 who had the greatest effect on the overall participation rates of women workers (table 20).

In the decade 1940 to 1950, changes in the woman labor force continued to follow the long-term pattern of an overall increasing participation rate with the emphasis on the older age groups. However, the pattern was somewhat more pronounced during this short period than during the preceding 50 years. Well over one-third as many women - 3.5 million - were added to the labor force during this one decade as during the previous 5 decades. Had women's participation in the labor force followed the same average rate of increase between 1940 and 1950 as during the previous 50 years, only about $2\frac{1}{2}$ million would have been added to the woman labor force. Likewise, if the participation rates of older women had not increased so significantly between 1940 and 1950,

the median age of women workers probably would have risen only 1 or 2 years rather than 4 years (table 20).

Labor Force Changes Since 1940

Before World War II women under 35 years of age outnumbered their elders in the woman labor force; and even at the height of the war (1945), they still predominated in the labor force. But, when the war was over, a greater proportion of these younger women left the labor force to take up duties of home and family, while many of the older women remained at work. Thus, in 1947 - for the first time - women 35 years and older outnumbered younger women workers. In 1953, these older women constituted 56 percent of the woman labor force; the number of women in the age groups 18 to 34 years in the labor force had decreased while all other age groups, even 65 years and over, increased in comparison with 1940 (table 21).

The proportions of women who work increased sharply in all age groups during World War II, reaching a peak in 1945. After the war, participation rates dropped for all age groups, but not so sharply for groups 35 years and over. In 1953, women in all age groups except 20 to 34

were participating in the labor force to a greater extent than in 1940; but significantly, only in the age groups 45 to 64 were women participating at a higher rate than in 1945. Today, therefore, a smaller proportion of the women in the child-bearing, child-rearing age groups are in the labor force than in 1940; while a much higher proportion of the women in older age groups are working (table 20).

Occupations

Almost half of the 18 million employed women in April 1953 were between the ages of 25 and 44 (table 23). More than half of these women were employed as clerical or factory workers, whereas slightly less than half of all women workers were so employed (table 24).

Clerical work is, of course, a very important field of work for women - more than one-fourth of all employed women were clerical or kindred workers in 1953. However, clerical

work as a field for women decreases in importance as age advances. Young women (14 to 24 years) are heavily concentrated in clerical work. Next to clerical work, young women are found in factory, private household work, or service work, but to a substantially lesser degree (table 24).

Although women 25 to 44 years of age outnumber all other age groups in clerical occupations (as they do in most occupations because of their larger numbers), they are almost as apt to be factory workers as clerical workers. This group, like young workers, also tends to be in service work next to clerical and factory work. However, professional work is almost as important to them as service work (table 24).

The next older group, 45 to 64 years of age, tends to spread more evenly over the occupational groups, with some concentration in clerical and factory work (table 24). Significant proportions of this group are also found in service work, professional work, and private household work - in that order of importance.

Elderly women, 65 years and over, are concentrated in private household work and service work. One-fourth of the employed women in this age group in 1953 were private household workers and one-fifth were service workers. Undoubtedly this is, in large part, due to the fact that women of advanced years may prefer the part-time schedules which frequently are possible in such work and, in addition, are not so well able to secure or hold the office jobs which are so popular among young women. On the other hand, we find that only in this elderly group is there a significant concentration in the group called "Managers, officials, and proprietors, except farm." Perhaps this is due to their mature years, length of experience in their chosen fields, or inheritance of businesses from their husbands. In addition to these three occupational groups, women 65 years and over are found also in professional work and factory work (table 24).

In summary, one might say that the young woman is most likely to be an office worker; the

mature woman, an office or factory worker; the older woman, an office, factory, or service worker; and the elderly woman, a private household or service worker (table 24).

Although the overall occupational distribution of women workers showed no significant changes between 1951 and 1953, there were more occupational shifts among older women than among young women. Young women (14 to 24 years) showed some movement out of service work into clerical work, while women 25 to 44 years of age moved out of clerical work and into factory and service work. Older women (45 to 64 years) moved into professional, clerical, and sales work as well as into the crafts field and left factory and private household jobs. Women 65 years and over shifted mostly into private household work but also into professional and clerical work, having moved out of the sales and crafts fields. All age groups showed some decrease in the group termed, "Managers, officials, and proprietors, except farm."

VII. MARITAL STATUS

Population Changes

Since 1940, the number of single women in the population has been steadily declining - from almost 14 million in 1940 to only 11 million in 1952, a decrease of more than 20 percent. During this same 12-year period, the number of married women in the population has steadily increased, from 30.1 million in 1940 to 38.7 million by 1952, an increase of $28\frac{1}{2}$ percent. There has also been an increase of 1.8 million widowed or divorced women in the population (table 25).

Reflecting these numerical changes, the marital distribution of the woman population today differs markedly from what it was in 1940. In 1952, only a fifth of the woman population 14 years and over were single, and two-thirds were married; in 1940, more than a fourth of the women were single, and only three-fifths were married. The proportion of widowed and divorced women in the population was about the same in 1952 as in 1940 - approximately 14 percent (table 26).

Labor Force Changes

Partly as a result of these population changes, the marital composition of the woman labor force has changed dramatically in the last 12 years. The population decline in single women was reflected by an almost equal decline in the number of single women in the labor force: From 6.7 million in 1940 to 5.5 million in 1952, a decrease of 18 percent. Among married women workers, on the other hand, there was an increase in number of more than 100 percent - from 5 million in 1940 to 10.4 million in 1952; and among widowed and divorced women there was a 40-percent increase in the number working, from slightly over 2 million to nearly 3 million during these years (table 25).

More than half of the woman labor force today is married. In 1940, however, married women formed only a little more than a third of all women workers. The proportion of single

women workers, by contrast, declined from almost a half in 1940 to considerably less than a third by 1952. The proportion of widowed and divorced women in the labor force, as in the population, has remained the same - about 15 percent of the woman labor force (table 26).

Population changes alone, however, do not account for the "new (married) look" of today's women workers, by comparison with 1940. Married women increased by 29 percent in the population during these years, but by more than 100 percent in the labor force because a much larger proportion of married women sought jobs outside of their homes during this period. In 1940, only 17 percent of the married women in the population were workers; but in 1952 about 27 percent of these women were workers. Among single women, and divorced and widowed women, on the other hand, the proportions in the labor force changed very little in these years - about one-half for single women and about one-third for widowed and divorced women (table 27).

Labor Force in Relation to Population

This phenomenal increase in the proportion of married women who work began during the years of World War II, when the proportion of married women who were working or seeking work increased from 17 percent in 1940 to 26 percent in 1944. These women,

of course, were needed as replacements for men who had left civilian jobs to serve in the Armed Forces, and many of these women were the wives of servicemen. Following World War II, there was a definite decline in the number and proportion of married women who were working, as men returned from the Armed Forces and families were reunited. By 1948, however, the participation rate for married women had again begun to increase, and by 1951 exceeded the World War II peak (table 27). Undoubtedly the primary impetus to this post-World War II increase in the proportion of married women who are working has been the need for married women's contributions to the economic solvency of their homes and families, as well as the common American desire for an improved standard of living. (See ch. X, Women as Heads of Families and Annual Income.)

The need for additional workers in the Nation's civilian labor force during World War II was responsible also for an increase in the proportion of single women who were working - from 48 percent in 1940 to 59 percent in 1944. However, this proportion returned to about its pre-war level following the war, and has remained fairly constant ever since (table 27). As a matter of fact, there are relatively few single women today who are not already working. In the age group 25 to 34 years, for example, 83 percent of all single women in the population

are in the labor force, as compared with only 27 percent of the married women of these ages, many of whom have young children. The World War II expansion in the proportion of single women who were working undoubtedly occurred chiefly among girls of school age (14 to 19 years) who, during the war years as today, comprised the bulk of single women not already in the labor force. (See ch. XI, Labor Reserve.)

Occupations

Regardless of marital status, women workers tend to concentrate in a few occupations: More than a third (37 percent) of the employed women in April 1952 were in clerical, sales and kindred jobs (of which almost 80 percent were clerical jobs); about a fifth were in service occupations; another fifth worked as operatives or on kindred jobs; and about a tenth were in professional or technical occupations. However, within these major concentrations marital status has some effect in determining the kind of occupation in which a woman finds employment (table 28).

Almost half (47 percent) of all employed single women were in clerical, sales or kindred

jobs in April 1952. This is understandable, of course, since single women workers are by-and-large younger women (having a median age of 25 years). Consequently, they are often new entrants to the labor market; relatively free from family responsibilities, and able to undertake the full-time, year-round work required in these jobs. For these reasons, they are frequently willing to accept the relatively low wage levels common to many clerical jobs. Furthermore, clerical jobs are apt to be full-year jobs which result in higher annual incomes than many service jobs; also, they require a shorter training period, relative to earnings, than professional and technical jobs; and they are considered by many to have more prestige than the "blue-collar" factory jobs. These factors undoubtedly explain why service occupations claim only 17 percent of all employed single women, professional and technical jobs only 16 percent, and operative jobs or factory work only 13 percent (table 28).

Among married women with husbands present, only slightly more than a third are clerical or sales workers, almost a fourth are operatives, about a fifth are service workers, and only a tenth are professional and technical workers.

It is impossible, of course, to generalize about the widely varying family responsibilities which this group of women carry; however, many, and especially those among them who have children, are likely to work intermittently during the year. (See ch. IX, Part-Time Employment.) Those factory jobs which are most commonly open to women often require no previous work experience or training, provide relatively short on-the-job training, and - relative to the training required - offer higher earnings than service jobs. These factors account, in part, for the relatively high proportion of married women who find employment as operatives (table 28).

Widowed, divorced, and separated women tend to concentrate in service jobs, which employ more than a third of this group. Another fourth are found in clerical or sales jobs, and a fifth are employed in factories. This is the group of women most likely to be forced into the labor market suddenly and

involuntarily, as they find themselves heads of families or faced with the necessity for self support. Service jobs are in many cases the only jobs available to them under these circumstances (table 28).

Because married women are more than half of all employed women, the proportion they form of the women employed in each of the major occupation groups is greater than that of either single women or widowed, divorced, and separated women, with two exceptions: Among professional and technical women, the proportion of single women is about as high as the proportion of married women (42 percent and 43 percent respectively). Among farmers and farm managers, more than half of the employed women are widowed, divorced, or separated. In general, married women form from two-fifths to a half of all employed women in each major occupation group except operatives and proprietors and managers where they constitute three-fifths; and farm laborers, where they form four-fifths of all women engaged in these occupations.

VIII. MOTHERS

Labor Force Participation Since 1940

Of the almost 19 million women in the labor force in April 1952, more than $5\frac{1}{4}$ million - about 3 out of 10 - were mothers of children under 18 years of age. This number was about $3\frac{1}{2}$ times as large as the number of mothers who were working in 1940 (table 29).

Almost one-fourth of all of the mothers in the population, with children under 18 years of age, were working in 1952. Exactly comparable data for 1940 are not available. However, it has been estimated that the $1\frac{1}{2}$ million mothers who were working in 1940 represented less than 10 percent of the mothers in the population at that time. In other words, in 1940, less than one-tenth of the mothers in the population, who had children under 18 years of age, were working; by 1952, almost one-fourth of such mothers were in the labor force (table 30).

Between 1940 and 1946, during the years of World War II, the number of working mothers more than doubled, and the proportion of mothers who were working increased about 10 percentage points. Furthermore, the end of the war did not bring about any reversal of this trend; for both the number and the proportion of working mothers continued to increase steadily (tables 30 and 31).

Ages of Children of Working Mothers

Of the $5\frac{1}{4}$ million working mothers in April 1952, about 2 million had one or more young children under 6 years of age. The remaining $3\frac{1}{4}$ million women had older children only (between the ages of 6 and 17 years). The 2 million mothers of young children represented a little more than 10 percent of the woman labor

force in 1952, whereas mothers of older children only, represented about 17 percent of the woman labor force (table 29).

Working outside of the home is, of course, most difficult for mothers of young children, and this is reflected in the proportion of those mothers who are so engaged, by comparison with mothers who have children of older ages only. Whereas a little more than a third of the mothers of children between the ages of 6 and 17 years were working, only about a sixth of the mothers of preschool age children were in the labor force in 1952. Furthermore, the increase during the post-war years in the proportion of working mothers who had young children has been less pronounced than the increase among those who had children of school age only (table 30).

Marital Status of Mothers

In view of the dual responsibility and physical strain involved for mothers who are employed outside of their homes, it may be assumed that the vast majority of mothers who work do so for economic reasons. This explains, in part, the tremendous difference in the proportion of working mothers among women who are living with their husbands by comparison with women who have children but who are widowed,

divorced, or separated. Among the latter group, more than half were in the labor force in 1952. Among women whose husbands were present, on the other hand, only a fifth were in the labor force (table 31).

Among mothers of young children, only about 14 percent whose husbands are present were in the labor force; and while there has been a steady increase in this proportion since 1946, the difference between 1946 and 1952 is one of only 4.5 percentage points. Among mothers who are widowed, divorced, or separated, on the other hand, two-fifths were in the labor force in 1952 and an even greater proportion in 1948, respectively 6 and 10 percentage points over 1946 (table 32).

In the population, 90 percent of all mothers are women whose husbands are present. Therefore, despite the tremendous differences in the participation rates of mothers by their marital status, those mothers whose husbands are present form four-fifths of all mothers in the labor force. And we must assume that, for many of these women economic reasons force them - as well as the widowed, divorced, and separated women - to accept the tremendous responsibilities of home, children, and outside job (table 31).

IX. PART-TIME EMPLOYMENT

Persons classified as part-time workers are those who ordinarily work at jobs for less than 35 hours per week. During 1951, about $10\frac{1}{2}$ million persons worked on a part-time basis. This group represented 15 percent of the 70 million persons who worked at some time during 1951 (table 33).

Part-time employment is more common among women than among men: One-fourth of the 24.6 million women who worked at some time during 1951 had part-time jobs, whereas less than a tenth of the 45.4 million men who worked during the year were on a short schedule (table 33).

Occupations Employing Part-Time Workers During 1951

Farm laborers and private household workers are the two occupation groups with the largest complement of part-time workers. Among women farm laborers almost two-thirds, and among men farm laborers about one-third were employed for less than 35 hours a week. Many of the farm laborers working on a part-time basis are unpaid family members who work as needed during busy periods on the family farms. (Unpaid family workers are considered as part of the labor force if they work as much as 15 hours a week on a family-operated farm or business.) Women on farms, of course, have much less opportunity for continuous full-time employment than do the women in urban communities (table 33).

Private household work is predominantly a woman's job; 98 percent of the part-time workers in this occupation are women. These workers often work by the hour or by the day in private homes; and during 1951, about 60 percent - or 3 out of every 5 household workers - were employed on a part-time basis, i.e., for less than 35 hours a week (table 33).

Sales work is another occupational group in which large proportions of part-time workers are found, particularly among women. Almost 40 percent of the women salespersons - though only 17 percent of the men so employed - were part-time workers during 1951. As with the retail trade industries which employ part-time sales women in large proportions, the service industries such as restaurants, beauty shops, etc., often find it advantageous to employ help on a part-time basis. Twenty-five percent of all women service workers other than in private households were working for less than 35 hours a week during 1951 (table 33).

Among clerical workers and operatives, the two largest woman-employing occupation groups, accounting for the employment of almost 50 percent of all working women, the proportion of part-time workers was smaller - only about 12 percent in each group - during 1951 (table 33).

Age of Part-Time Workers During 1951

Among women part-time workers, almost 60 percent were between the ages of 25 and 54 years. Among men part-time workers, on the other hand, only 20 percent were found in these ages during 1951. Young boys, between the ages of 14 and 17 years, and older men, 55 years and over, formed the bulk of the male part-time labor force.

Among both young women and men of 14 to 17 years, almost two-thirds of all persons who worked at some time during 1951 were employed on a part-time basis. A high percentage of girls and boys of this age group are enrolled in school, which accounts for the prevalence of part-time work among them (table 34).

Again, in the 18-to-24-year age group, the proportion of young women who worked part time was about the same as the proportion of young men - 15 percent among women and 12 percent among men. This is the age group of greatest full-time labor force participation among women (table 34).

For women in the age groups 25 to 64 years, however, the proportion of women part-time workers reflects the fact that many women have child-rearing or homemaking responsibilities and, therefore, often cannot accept full-time jobs. Most of the men of these ages, on the other hand, work at full-time, year-round jobs.

In the older age groups, 65 years and over, the proportion of women workers in part-time jobs is again much higher than the proportion of men workers in such jobs. Job opportunities for both

men and women in these ages are, of course, limited. In addition, among women, many have had no previous or recent work experience which would qualify them for full-time jobs; among men, past the traditional retirement age of 65 years, also, opportunities for full-time employment are limited (table 34).

Work Patterns by Marital Status During 1950

Not marriage per se, but presence or absence of young children in the home, is the key factor in determining not only whether a woman works full or part time, but also - among full-time workers - whether she works throughout the year or on an intermittent basis. Among married women with no children under 18 years, and among widowed, divorced, and separated women, and single women, about a fourth of those who worked were on a part-time basis during 1950. (Comparable data for 1951 are not available.) Among women with children, however, almost two-fifths worked on a part-time basis (table 35).

Three-fourths of all married women workers without children, as well as of the widowed, divorced, and separated women, and the single women who were employed, worked at full-time jobs during 1950. Furthermore, more than half of the women in these marital groups worked for at least half a year; and at least two-fifths of them were full-time, year-round workers (table 35).

Among women with children, on the other hand, only about two-fifths of those with children between 6 and 17 years, and only a fourth of those with children under 6 years worked at full-time jobs for a half year or more (table 35).

X. INCOME

Even though there are more job opportunities for women and more women are working today than before World War II, women's income from their jobs has increased less than has men's income, since 1939. In 1951, the median income of working women was only about two-fifths that of men, whereas in 1939 it was nearly three-fifths of men's.

From these facts on income it appears that the large numbers of women who have entered the labor force throughout the past decade have found employment in those lower-paying jobs which were always open to women or in those which were vacated by men who moved into the higher-paying jobs created by war and defense conditions. Furthermore, women apparently have remained in these lower-paying jobs; consequently men's income from wages and salaries has increased at a greater rate than women's.

Wages and Salaries

Between 1939 and 1951 the median wage and salary income of women, like that of men, showed a significant increase - from \$555 per year to \$1,361 per year. In other words, women's income increased almost $1\frac{1}{2}$ times. However, during this time men's income increased slightly more than 2

times, thereby widening the traditional gap between women's and men's wage and salary income. Whereas women's income amounted to 59 percent of men's in 1939, it amounted to only 44 percent of men's in 1951 (table 36).

It is interesting to note that war and defense conditions did not result in any increase in women's income in relation to men's. As a matter of fact, there was a substantial decrease in women's income relative to men's between the prewar year of 1939 and the postwar year of 1945. This was followed by a small increase in women's relative earnings in 1947; and again, gradual decreases each year from 1948 through 1951. These developments suggest that war and defense periods drew many younger men from lower-paying jobs into military service, and provided men in civilian employment with significantly better job opportunities than women. Furthermore, men were successful in keeping these jobs (table 36).

The proportion of women with wage or salary incomes whose incomes from this source were under \$2,000 decreased by 30 percentage points between 1939 and 1951; nevertheless,

67 percent of all women wage or salary workers in 1951 still had incomes below that amount. By contrast, only 27 percent of all men wage or salary workers had incomes under \$2,000. Whereas women in the \$5,000 and over group formed less than one-half of 1 percent of all women wage and salary workers in 1939 and 1951, men in this group increased by 11 percentage points between these years, and had become 12 percent of all men wage and salary workers by 1951 (table 36).

The widening of the gap in wage and salary incomes of women and men is further evidenced by comparative income data for six occupational groups. In all of these occupational groups except two - professional and technical workers and managers, officials, and proprietors - increases in men's earned incomes between 1939 and 1951 exceeded those in women's. This is particularly important in view of the fact that the two groups excepted employ only about 15 percent of all women workers. Proportionately speaking, therefore, the important woman-employing occupational groups are providing greater increases in wages to men than to women (table 37).

These facts are undoubtedly significant in considering the persistent labor shortages in occupations frequently filled by women. For

example, although women have continued to dominate the clerical field, there is still a shortage of such workers; yet, at the same time, men's incomes in these occupations are increasing more rapidly than women's.

In none of the six occupational groups in 1951 did women's income amount to as much as two-thirds of men's; and in the sales worker group, women's income was only one-third of men's (table 37).

Husband-Wife Income

As might be expected, families in which both husband and wife work have higher incomes than those in which only the husband works. In 1952, only a fifth of the families with the wife in the labor force as compared to a third of those with the wife not in the labor force had total money incomes under \$3,000 dollars for the previous year. Almost half of the families with husband and wife working, but only a fourth of those with the wife not working, had incomes above \$5,000. Total money income includes income from self-employment, interest, rents, annuities, etc., in addition to wage and salary income (table 38).

Both the extent to which wives participate in the labor force and the level of wives' incomes when they do work are directly related to the husbands' incomes. The percent of wives in the labor force decreases markedly in accordance with the husbands' incomes. Whereas about one-third of the wives were working in families in which the husbands' incomes were between \$1,000 and \$3,000, only about one-seventh of the wives were working when their husbands' incomes were \$6,000 or more. Furthermore, 1951 data show that the median income of working wives of husbands with incomes of \$4,000 or more was close to \$2,000, while incomes of wives whose husbands earned less than \$2,000 a year was only about \$1,000 (table 40).

Among the reasons for these relationships may be the fact that husbands and wives tend to have similar backgrounds, education, experience, and work qualifications; furthermore, wives of higher-income men may be reluctant to accept low-paying jobs, since their need for additional income is less pressing than in low-income families.

In 1951, median income in the United States was lowest for families with a female head, and highest for families having a male head with wife

in the labor force. However, even when the wife was not in the labor force, families headed by a man had substantially higher median incomes than families headed by a woman, with a difference of more than \$1,400 per year (table 39).

The significance of this discrepancy in family income becomes apparent when one considers that there are more than 4 million families, 1 out of every 10, in the United States with a woman head. Three-fourths of these families are located in urban areas, where the difference in family incomes is even more marked than in the country as a whole: In urban areas, where almost 1 out of every 8 families has a woman head, the median income of male-headed families with the wife in the labor force is almost twice that of families with a female head. Even where the wife is not in the labor force, the income of urban families with a male head exceeds that of families with a female head by 60 percent, or \$1,500 (table 39). Clearly then, low incomes of women, relative to men, affect not only the women themselves, but also the large number of families for which these women hold sole or primary responsibility.

Residence

In urban areas, women's total money income - including money from wages, salary, self-employment, rents, interest, etc. - averaged about two-fifths of that of men in 1951. In rural areas, women's total money income averaged less than a third of men's (table 41). In rural areas, of course, about two-thirds of the woman labor force is composed of unpaid family workers, many of whom work only during the planting or harvesting seasons on the family farms. (See ch. II, Industry and Class of Worker.)

The proportion of unpaid family workers among the woman labor force in farm areas is considerably greater than the proportion of these workers among the male labor force in these areas. These differences account, in part, for the fact that the total money income of women in rural-farm areas averaged only 35 percent of the money income of women in urban areas in 1951, whereas men in rural areas had a median money income of nearly half (46 percent) that of men in urban areas. However, for both women and men in rural areas total money income excludes payments in kind, and urban-rural comparisons must be evaluated with this in mind.

Age

Almost twice as many men as women had some money income in 1951. Among persons 14 years of age and over, slightly more than 4 out of every 10 women as compared with 9 out of every 10 men had some money income that year. For both men and women, the median income figure was lowest for the 14 to 20 year old group. For both, incomes increased after 20 years of age; however, women's median income began to diminish at 35 years while men's did not begin to decrease until 45 years of age. These data reflect the fact that many women 35 years and over have family responsibilities and so are not in the labor force, and, also, that men - by comparison with the women who are working - are more likely to work in fields which permit them greater opportunities for advancement as they acquire seniority and experience (table 42).

Whereas men's and women's median income was about the same in the 14 to 20 year group, men's income increasingly exceeded women's in the upper age groups, ranging from about $1\frac{1}{2}$ times as large as women's at 20 to 25 years to 3 times women's at 55 to 65 years. At 65 years and over, however, men's median income dropped to only twice that of women's (table 42).

XI. THE LABOR RESERVE - WOMEN NOT IN THE LABOR FORCE

Expansion of the Nation's Labor Force

In April 1953, there were about 39½ million women 14 years and over who were not in the labor force. At the same date, there were 9 million men who were not working. The women, therefore, constituted the largest single source for increasing the Nation's work force in the event of expanded labor needs (table 43).

However, about 4 percent of the women not in the labor force were unable to work because of disability, advanced age, or other reasons, and another 10 percent were in school. More than 80 percent of those in school were between the ages of 14 and 17 and, therefore, would normally be encouraged to complete their education before entering the labor force. Eliminating the young women who were in school and those unable to work, there remain some 35 million non-working women who would be available as

a possible source of additional workers, and the vast majority of these are classed as "keeping house" (table 43).

Many of these women who are "keeping house," however, are 65 years of age and over; and others are mothers who must care for their children. It is, therefore, not reasonable to assume that all of the 34 million women in this group could be brought into the labor force, if necessary. Rather, this number represents about the entire pool of women not now in the labor force from which additional workers might be made available to an expanded economy.

A more practical estimate of the supply of women actually available would not include mothers responsible for the care of children or elderly women. This leaves a primary labor reserve of about 11 million

women between the ages of 18 and 64, having excluded the women 65 years and over and an estimated 17 million mothers. Thus, it is estimated that approximately 28 percent of all the women 14 years and over who were not working in 1953 would have been available for labor force expansion, if necessary (table 43).

Previous Work Experience

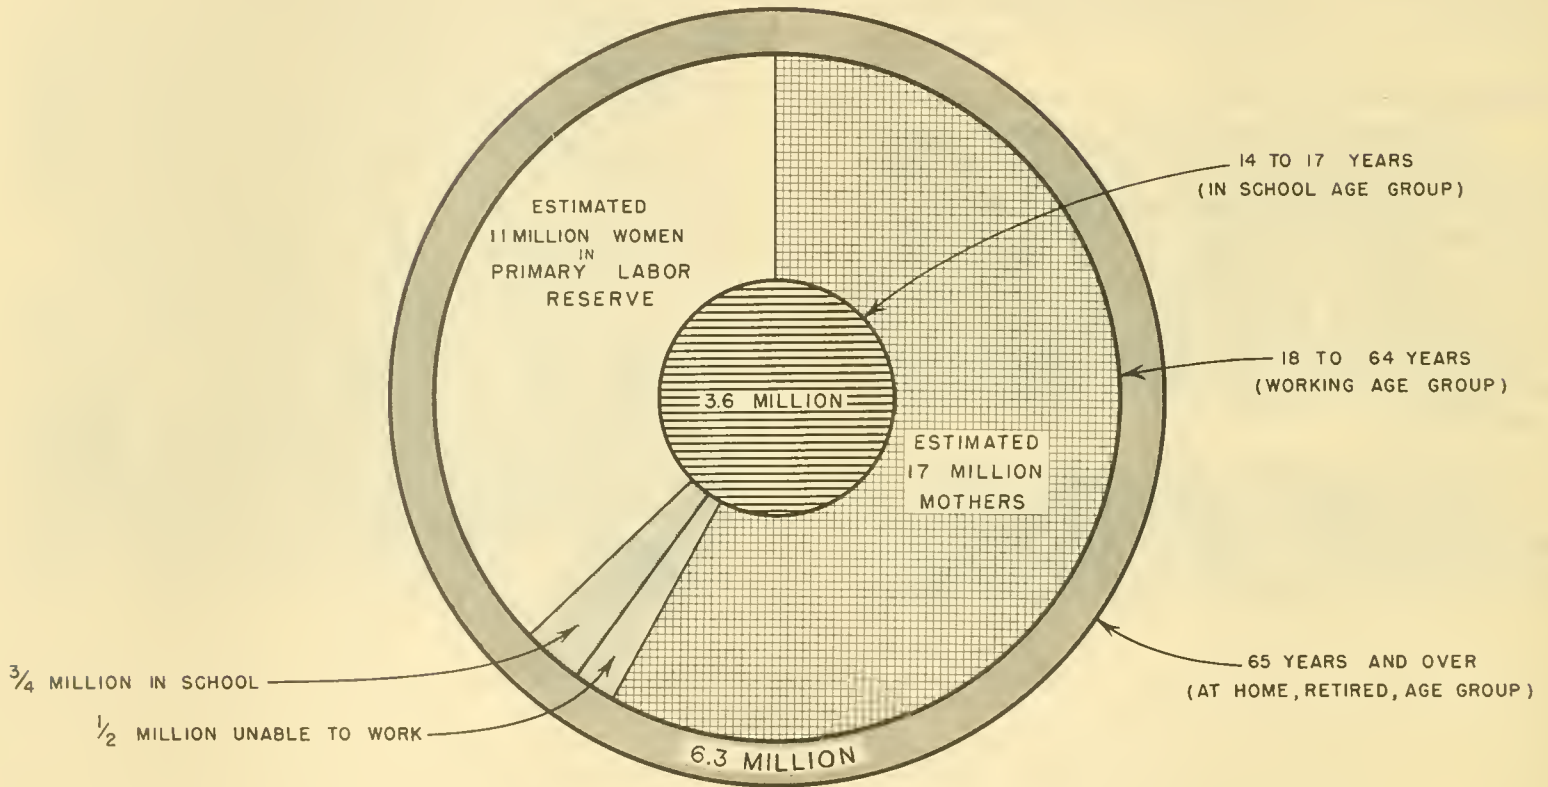

In considering the utilization of women in the labor reserve, it is important to take account of their previous work experience, particularly if such work experience was recent. A March 1951 Bureau of the Census survey of the labor reserve revealed that almost 1 out of every 3 of the women who were not then in the labor force had had some previous work experience during or after World War II (table 45).

For a majority of these women - almost 7 million - their previous work experience was fairly current, that is, since 1945. Some 4 million out of the total 11 million

women had work experience during World War II, and also many of those with current work experience had worked during the war period (table 45).

Slightly more than 6 thousand of the women with previous work experience were in the age group 20 to 34 years, while the remainder were about evenly divided between the age groups 35 to 44 and 45 to 64. Furthermore, the 20 to 34 year age group included almost 4 times as many women with current work experience and twice as many women with experience prior to 1945 as either of the other two groups. Obviously, therefore, it was women between the ages of 20 and 34 years who made up the bulk of the experienced labor reserve and, particularly, the currently experienced reserve. However, it should be remembered that it is this age group, also, which is most likely to be responsible for the care of young children; and if their services are needed in the Nation's labor force, account will have to be taken of the threefold responsibility - for home, children, and job - which these women would be assuming.

XII. EDUCATION

Years of School Completed

Only about 2 percent both of women and of men 25 years and over in the population in 1950, compared with 4 percent in 1940, had had no schooling. In addition, about a fifth of the women and a fourth of the men 25 years and over in 1950, but a fourth of the women and three-tenths of the men in 1940 had less than an 8th grade education (table 46).

On the whole, women have had about half a year more of schooling than men in this country. For women, the median school years completed was 9.6 in 1950; for men, it was 9.0 years. The bulk of this difference is accounted for by the fact that two-fifths of the women, but only one-third of the men 25 years and over had some high-school education in 1950. But, on the other hand, a slightly higher proportion of men (14 percent) than

of women ($12\frac{1}{2}$ percent) had completed some college training. As these data indicate, college-trained persons are still a small minority of the adult population: Only $2\frac{1}{4}$ million women and 3 million men 25 years and over had completed 4 or more years of college by 1950 (table 46).

Employment of School Enrollees

In 1951, there were about $4\frac{1}{4}$ million women and $4\text{-}3/4$ million men between the ages of 14 and 24 years who were enrolled in school. Among the 14 to 17 year olds, the proportion of girls and boys in school was the same. In the college-age groups, however, the proportions of men in school were considerably higher than the proportions of women. Only 9 percent of all women 18 to 24 years old, but 19 percent

of all men of these ages, were in school in 1951 (table 47).

The implications of this pattern of school attendance for future employment prospects for men and women are numerous. Men, to a much greater extent than women, are clearly fitting themselves for jobs which require longer training and offer higher salaries. In this connection, two facts concerning women's employment should be kept in mind: In comparison to men, women have less choice of employment fields, and this situation tends to discourage women from spending long periods in acquiring the training necessary for higher-level jobs. Furthermore, in fields which require advanced training and are traditionally open to women - teaching, nursing, social work, etc. - average earnings are almost always substantially lower than those in professions where men predominate.

Data on employment of students further indicate that higher proportions of young men than of young women are employed while they are still in school. Only 30 percent

of the young women 20 to 24 years, but almost 40 percent of the young men in these ages, who were in school in 1951, were simultaneously employed. This work experience acquired by men during their school years undoubtedly assists in qualifying them for additional training and employment opportunities when they have finally completed their schooling. (table 47).

College Degrees Earned by Women

In 1951-52, women earned about one-third of all college degrees conferred that year, or about double the proportion in 1890, the first year for which this information is available. The proportion which women have formed of all college graduates has fluctuated considerably in the past 60 years. From less than a fifth of all graduates in 1890 they had become a third of the total by 1920. During the depression of the 30's, about 2 out of 5 graduates were women. During World War II, of course, when vast numbers of young men were in the armed services, women were more than half of all college graduates. Following the war, their number increased, but their proportion dropped to about a fourth, as

many veterans availed themselves of the opportunity to obtain a college education (table 48).

Field of Study in College Training

In the school year 1951-52, women received college degrees in more than 60 different fields of study. However, the bulk of these degrees were concentrated in the field of education, which accounted for almost 40 percent of all college degrees earned by women. Quite obviously, a substantial number of college women - more than 45 thousand - were preparing themselves for teaching, an occupation in which women have predominated for many years. Apparently, job opportunities for women still are not broad enough to change materially the college-educated woman's

choice of teaching as a career, any more than they have changed the less-than-college-educated woman's choice of clerical work (table 49).

Next to education, the most important field for college women was English; but this accounted for only 7 percent of all women graduates. These, together with home economics (7 percent), business and commerce (5 percent), and nursing and music (each 4 percent), account for almost 65 percent of all college-trained women who graduated in 1951-52. Each of the remaining fields of study accounted for 3 percent or less of the 125,500 woman graduates. Thus, there is little diversification in the kinds of specialization which college-trained women undertake (table 49).

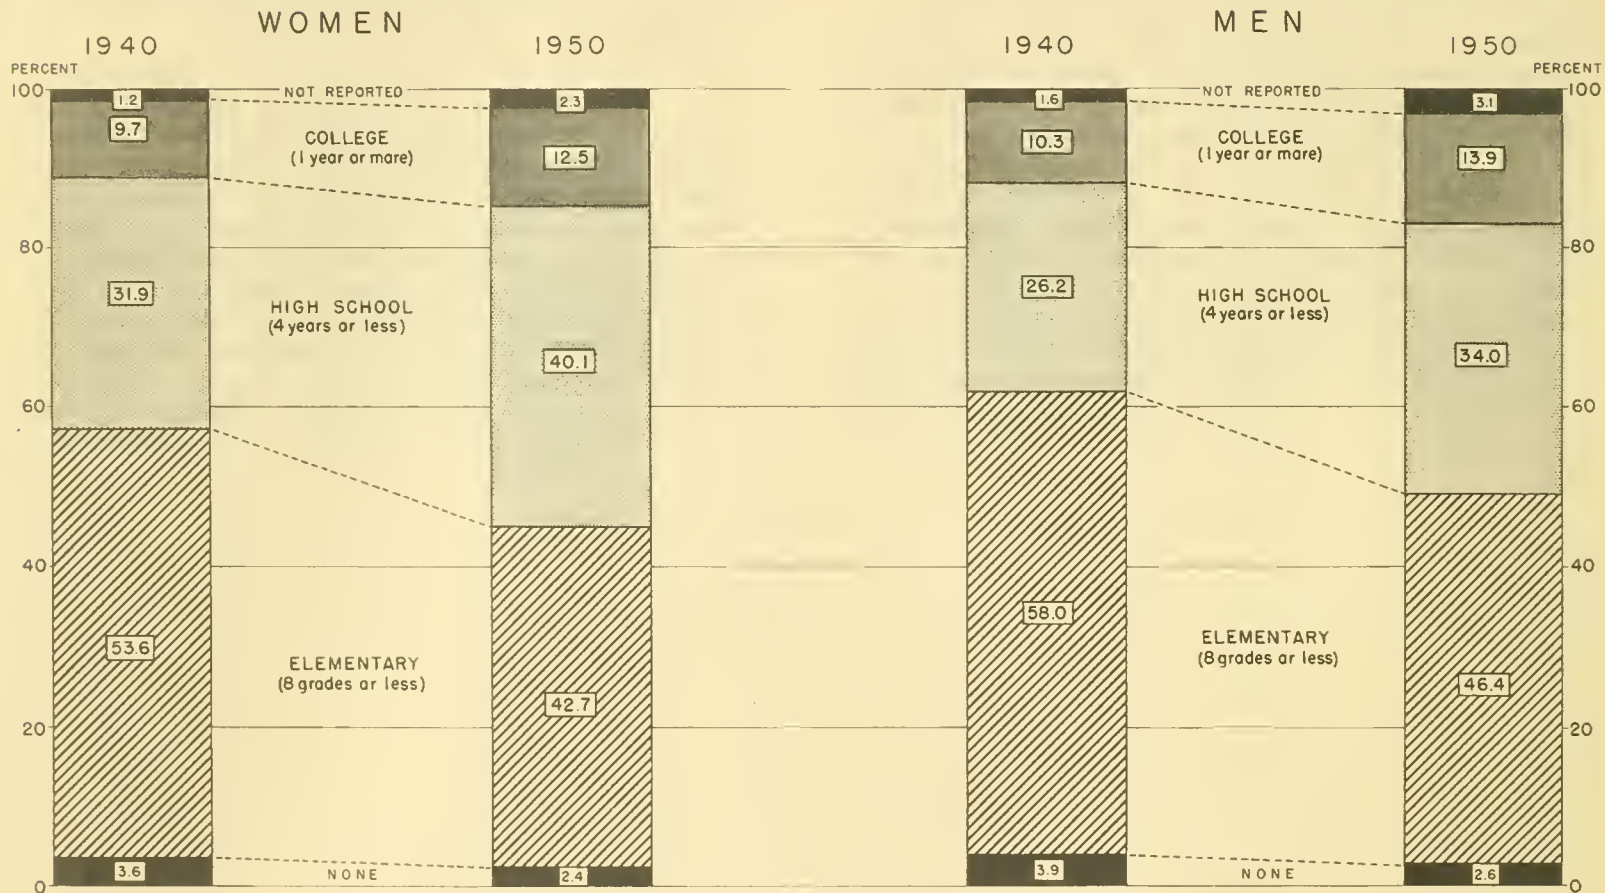

Men outnumbered women in all but 10 of the fields of study in which college degrees were conferred in 1951-52. At the top of the list of women's specialized fields were nursing and home economics in which 99 percent of the degrees were earned by women. Women also outnumbered men in the fields of library science, modern languages, education, social work, fine arts, English, sociology, and music - in other words, in liberal arts training primarily.

Women earned less than 10 percent of the degrees conferred that year in the following 20 fields of study: Agriculture, anatomy, animal husbandry, architecture, dentistry, engineering, entomology, forestry, geology, industrial arts, law, metallurgy, meteorology, military or naval science, optometry, osteopathy,

pharmacy, physical sciences, physics, and veterinary medicine. Interestingly enough, none of these fields fall in the general categories of liberal arts or social studies; almost all of them are specialized fields in the natural and physical sciences or in engineering.

From these facts it may be concluded that men, in acquiring college training, tend toward those highly specialized fields of study which relate most directly to job opportunities in industry. The majority of women, on the other hand, continue to choose those fields of study which provide more general education and culture, and which, therefore, equip them for family and community life as much as for paid work.

TECHNICAL NOTE

Data compiled by the U. S. Bureau of the Census, which have been used in this report, relate to persons 14 years and over in the population and the labor force, unless otherwise indicated in the table.

Where long-term trends are shown (tables 1, 19, and 20), figures for each year are from the decennial census of the United States. These data were obtained by a complete enumeration of the population, both civilian and military, once every 10 years. In all other tables showing census data, figures for each year are based on the monthly sample of the Bureau of the Census. These estimates are obtained by personal interview with individual members of a sample of households, and are designed to provide current information on the work status of the population, classified into broad social and economic groups. The estimates exclude inmates of institutions and members of the Armed Forces.

The number of persons in the labor force as enumerated in the 1950 decennial census is generally considered to be an under-enumerated figure, particularly with regard to teen-agers and women 25 years and over. In April 1950, the estimate of civilian persons, both men and women, in the labor force based on the monthly sample differed from the number of civilians enumerated in the 1950 census by some 3 million; i.e., the decennial census figure was about 5 percent below that obtained from the sample. Greatest differences were found in the numbers of women and of young persons reported as in the labor force. For example, the sample survey estimated 18 million women in the labor force, whereas the decennial census enumerated only $16\frac{1}{2}$ million women. Preliminary results of the analysis of these differences indicate that enumerators employed in obtaining the estimate for the sample survey reported more completely on the employment of all groups in the population. The estimated figure, therefore, is considered more accurate than that obtained from the total enumeration. Where long-term trends are involved, however, 1950 decennial census figures have been used in this report because they are considered more comparable with figures from earlier decennial censuses than are the more accurate figures obtained from the monthly sample of the labor force.
